Visualisation:

Significance:

This interactive map of Denmark shows students favourite leisure spots around the country, in a clustered setup with pop-up notes on hover, showing A): type of spot/venue B): brief description of the place.

It is used to answer the research question: "Which area of Denmark holds most positive sentimental value amongst university students in 2026?"

The map can help us visualize and easily access which regions of the country attracts most positive mentions in the above mentioned survey, without having to evaluate on each individual datapoint in a larger dataset. It is clearly observed that the region corresponding to "Region Midt", has most markers/mentions. What the map does not show in the current clustered form, is the precise distribution of these locations throughout the region, meaning we only have a rather superficial view. It also does not take into account statistical bias. The survey is made amongst university students in Aarhus, and so we could plausibly expect a regional bias, which indeed seems to be true! On closer inspection of the map, it appears that in fact most of the locations are in the city of Aarhus itself. Case in point, visualizations and maps like these must be used in conjunction with background knowledge and bias reflection, AKA close reading, to be useful and factual in answer.
